## Measurement of the ZZ production cross section and search for anomalous couplings in $2\gamma 2\gamma$ final states in pp collisions at $\sqrt{s}=7$ TeV

CMS Collaboration ; Chatrchyan, S ; Khachatryan, V ; Amsler, C ; Chiochia, V ; De Visscher, S ; Favaro, C ; Ivova Rikova, M ; Millan Mejias, B ; Otiougova, P ; Robmann, P ; Snoek, H ; Tupputi, S ; Verzetti, M ; et al

Abstract: A measurement is presented of the ZZ production cross section in the  $ZZ \rightarrow 2\gamma 2\gamma$  decay mode with  $\gamma\gamma = e^+e^-$  and  $\gamma\gamma = \mu^+\mu^-$ , in proton-proton collisions at  $\sqrt{s}=7$  TeV with the CMS experiment at the LHC. Results are based on data corresponding to an integrated luminosity of 5.0 fb<sup>-1</sup>. The measured cross section  $\sigma(pp \rightarrow ZZ) = 6.24 \pm 0.86 \text{ (stat.)} \pm 0.41 \text{ (syst.)} \pm 0.14 \text{ (lumi.) pb}$  is consistent with the standard model predictions. The following limits on ZZZ and ZZ anomalous trilinear gauge couplings are set at 95% confidence level:  $-0.011 < f_4 < 0.012$ ,  $-0.012 < f_5 < 0.012$ ,  $-0.013 < f_6 < 0.015$ , and  $-0.014 < f_7 < 0.014$ .

# Measurement of the ZZ production cross section and search for anomalous couplings in $2\ell 2\ell'$ final states in pp collisions at $\sqrt{s} = 7$ TeV

The CMS Collaboration\*

## Abstract

A measurement is presented of the ZZ production cross section in the  $ZZ \rightarrow 2\ell 2\ell'$  decay mode with  $\ell = e, \mu$  and  $\ell' = e, \mu, \tau$  in proton-proton collisions at  $\sqrt{s} = 7$  TeV with the CMS experiment at the LHC. Results are based on data corresponding to an integrated luminosity of  $5.0 \text{ fb}^{-1}$ . The measured cross section  $\sigma(\text{pp} \rightarrow \text{ZZ}) = 6.24^{+0.86}_{-0.80} (\text{stat.})^{+0.41}_{-0.32} (\text{syst.}) \pm 0.14 (\text{lumi.}) \text{ pb}$  is consistent with the standard model predictions. The following limits on ZZZ and  $ZZ\gamma$  anomalous trilinear gauge couplings are set at 95% confidence level:  $-0.011 < f_4^Z < 0.012$ ,  $-0.012 < f_5^Z < 0.012$ ,  $-0.013 < f_4^\gamma < 0.015$ , and  $-0.014 < f_5^\gamma < 0.014$ .

The study of diboson production in proton-proton collisions provides an important test of the standard model (SM). Many extensions of the SM predict new scalar, vector, or spin-2 particles that decay into a pair of W or Z bosons. In addition, these final states are sensitive to the self-interactions among the gauge bosons via trilinear gauge couplings (TGCs). These couplings are the direct consequence of the non-Abelian  $SU(2) \times U(1)$  gauge symmetry of the SM and are a necessary ingredient to construct renormalizable theories. The values of these couplings are fully determined in the SM by the gauge structure of the Lagrangian. Therefore, any deviation of the observed coupling strength from the SM prediction would indicate the presence of new physics. This deviation would be manifested as a change in the production cross section, especially for energetic heavy gauge bosons.

In the SM, ZZ production proceeds via the  $t$ - and  $u$ -channel  $q\bar{q}$  scattering diagrams, and via gluon-gluon fusion. The presence of anomalous neutral trilinear couplings (ATGCs) would lead to a sizable enhancement of ZZ final states via  $s$ -channel  $q\bar{q}$  scattering. A model featuring such couplings can be constructed by means of an effective Lagrangian [1]. In this parametrization, two ZZZ couplings and two ZZ $\gamma$  couplings are allowed by electromagnetic gauge invariance and Lorentz invariance for on-shell Z bosons. The couplings are parametrized by two CP-violating ( $f_4^{Z,\gamma}$ ) and two CP-conserving ( $f_5^{Z,\gamma}$ ) complex parameters, which are zero in the SM.

Measurements of the ZZ cross section were previously performed at the Tevatron [2, 3] and the Large Hadron Collider (LHC) [4, 5]. A first measurement of the ZZ cross section at center-of-mass energy  $\sqrt{s} = 7$  TeV by the Compact Muon Solenoid (CMS) Collaboration in the decay mode  $ZZ \rightarrow 2\ell 2\ell$ , where  $\ell$  is either e or  $\mu$ , is presented in Ref. [4]. The measured cross section  $\sigma(\text{pp} \rightarrow ZZ)\mathcal{B}(ZZ \rightarrow 2\ell 2\ell) = 28.1^{+4.6}_{-4.0}(\text{stat.}) \pm 1.2(\text{syst.}) \pm 1.3(\text{lumi.}) \text{ fb}$  agrees well with the SM prediction of  $27.9 \pm 1.9 \text{ fb}$ . In this Letter, we present an extended measurement of the ZZ production cross section based on the decay mode  $2\ell 2\ell'$ , where  $\ell'$  is e,  $\mu$ , or  $\tau$ . If a  $\tau$  is present in the final state, one Z is required to decay into  $e^+e^-$  or  $\mu^+\mu^-$ , and the second Z into  $\tau^+\tau^-$  in four possible final states:  $\tau_h\tau_h$ ,  $\tau_e\tau_h$ ,  $\tau_\mu\tau_h$ , and  $\tau_e\tau_\mu$ , where  $\tau_h$  represents a  $\tau$  decaying hadronically, while  $\tau_e$  and  $\tau_\mu$  indicate taus decaying into an electron and a muon, respectively. The presence of four leptons in the final state provides a clean signature with only a small contribution from background processes. The background sources include reducible contributions from  $Zb\bar{b}$  and  $t\bar{t}$  processes, where the final states contain two isolated leptons and two b jets with secondary leptons, and from Z+jets and ZW+jets processes where the jets are misidentified as leptons.

In this Letter, we also present a search for the neutral ZZZ and ZZ $\gamma$  ATGCs. Previous studies on neutral ZZZ and ZZ $\gamma$  ATGCs were performed at LEP2 [6–10], the Tevatron [11], and the LHC [5]. The most restrictive limits were set in Ref. [5],  $-0.07 < f_{4,5}^Z < 0.07$  and  $-0.08 < f_{4,5}^\gamma < 0.08$ , with a data set corresponding to an integrated luminosity of  $1 \text{ fb}^{-1}$  of pp collisions at  $\sqrt{s} = 7$  TeV.

The measurements presented here are based on data collected in 2010 and 2011 with the CMS experiment at the LHC at  $\sqrt{s} = 7$  TeV, corresponding to an integrated luminosity of  $5.0 \pm 0.1 \text{ fb}^{-1}$ . A set of Monte Carlo (MC) event samples is used to simulate signal and background events. The ZZ production via  $q\bar{q}$  is generated at next-to-leading order (NLO) with POWHEG 2.0 [12–14], while other diboson processes (WW, WZ, Z $\gamma$ ) are generated with PYTHIA 6.424 and MADGRAPH [15]. The  $gg \rightarrow ZZ$  contribution is estimated using events generated with the  $gg2ZZ$  code [16]. The Z+jets samples, namely  $Zb\bar{b}$ ,  $Zc\bar{c}$ , and Z+light jets, are generated with MADGRAPH. The  $t\bar{t}$  events are generated at NLO with POWHEG. For leading-order generators, the default set of parton distribution functions (PDFs) used to produce these samples is CTEQ6L [17], while CT10 [18] is used for NLO generators. Finally, for the modeling of

ATGCs, the SHERPA generator version 1.2.2 is used [19]. The  $\tau$ -lepton decays are generated with TAUOLA [20]. All events are processed through a detailed simulation of the CMS detector based on GEANT4 [21] and reconstructed with the same algorithms as used for data.

A detailed description of the CMS detector can be found elsewhere [22]. The central feature of the CMS apparatus is a superconducting solenoid of 6 m internal diameter, providing a magnetic field of 3.8 T. Within the field volume are the silicon pixel and strip tracker, the crystal electromagnetic calorimeter (ECAL), and the brass/scintillator hadron calorimeter (HCAL). Muons are measured in gas-ionization detectors embedded in the steel flux return yoke of the magnet. CMS uses a right-handed coordinate system, with the origin at the nominal interaction point, the  $x$  axis pointing to the center of the LHC ring, the  $y$  axis pointing up (perpendicular to the plane of the LHC ring), and the  $z$  axis along the counterclockwise-beam direction. The polar angle  $\theta$  is measured from the positive  $z$  axis and the azimuthal angle  $\phi$  is measured in the  $x$ - $y$  plane. Variables used in this analysis include the pseudorapidity  $\eta = -\ln[\tan(\theta/2)]$  and the transverse momentum  $p_T = \sqrt{p_x^2 + p_y^2}$ . The ECAL is designed to have both excellent energy resolution and high granularity, properties that are crucial for reconstructing electrons and photons produced in  $\tau$ -lepton decays. The ECAL is constructed with projective lead tungstate crystals that provide coverage in pseudorapidity  $|\eta| < 1.48$  in a barrel region and  $1.48 < |\eta| < 3.00$  in two endcap regions (EE). A preshower detector consisting of two planes of silicon sensors interleaved with a total of  $3X_0$  of lead is located in front of the EE. The energy resolution is 3% or better for the range of electron energies relevant for this analysis. The tracker measures charged particle tracks within the range  $|\eta| < 2.5$ . It consists of 1440 silicon pixel and 15 148 silicon strip detector modules, and provides an impact parameter resolution of  $\sim 15 \mu\text{m}$  and a transverse momentum resolution of about 1.5% for 100 GeV particles. The reconstructed tracks are used to measure the location of interaction vertices. The spatial resolution of the reconstruction is  $\sim 25 \mu\text{m}$  for primary vertices with more than 30 associated tracks [23]. The barrel region of the muon system is instrumented with drift tubes, and the endcap regions with cathode strip chambers. In both regions, resistive-plate chambers provide additional coordinate and timing information. Muons are reconstructed in the range  $|\eta| < 2.4$ , with a typical  $p_T$  resolution of  $\sim 1\%$  for  $p_T = 40 \text{ GeV}$ .

At the trigger level, the selected events are required to have either at least two electrons, one with  $p_T > 17 \text{ GeV}$  and the other with  $p_T > 8 \text{ GeV}$ , or at least two muons, one with  $p_T > 13 \text{ GeV}$  ( $p_T > 17 \text{ GeV}$  for high instantaneous luminosity data-taking periods) and the other with  $p_T > 8 \text{ GeV}$ .

Electrons are reconstructed within  $|\eta^e| < 2.5$  and with  $p_T^e > 7 \text{ GeV}$  by combining information from the ECAL and tracker [24, 25]. Electron identification requirements rely on the electromagnetic shower shape and other observables based on tracker and calorimeter information. The selection criteria depend on  $p_T^e$  and  $|\eta^e|$ , and on a categorization according to observables that are sensitive to the amount of bremsstrahlung emitted along the trajectory in the tracker. Muons are reconstructed [26] within  $|\eta^\mu| < 2.4$  and  $p_T^\mu > 5 \text{ GeV}$  with information from both the tracker and the muon spectrometer. The track must have more than 10 hits in the silicon tracker [22] to ensure a precise measurement of the momentum. The efficiencies are measured in data, using a tag-and-probe technique [27] based on an inclusive sample of  $Z \rightarrow \ell^+ \ell^-$  events. The measurements are performed in several ranges of  $p_T^\ell$  and  $|\eta^\ell|$ . The product of reconstruction and identification efficiencies for electrons in the ECAL barrel (endcaps) varies from about 68% (62%) for the  $p_T^e$  range 7–10 GeV, to 82% (74%) at  $10 < p_T^e < 20 \text{ GeV}$ , and reaches up to 90% (89%) at  $p_T^e > 20 \text{ GeV}$ . The muons are reconstructed and identified with efficiencies above 98%.

Since the  $ZZ$  final state is expected to have only a small contribution from background pro-

cesses, the algorithms are tuned to maximize the lepton-reconstruction efficiency, resulting in an increased lepton-misidentification rate. A particle-flow (PF) technique [28] is used for  $\tau_h$  reconstruction. In the PF approach, information from all subdetectors is combined to reconstruct and identify particles produced in the collision. The particles are classified into mutually exclusive categories: charged hadrons, photons, neutral hadrons, muons, and electrons. These particles are used to reconstruct the  $\tau_h$  candidates with the “hadron plus strip” (HPS) algorithm [29], which is designed to optimize the performance of  $\tau_h$  identification and reconstruction by considering specific  $\tau_h$  decay modes. The neutrinos produced in all  $\tau$  decays escape detection and are ignored in the  $\tau_h$  reconstruction. The algorithm provides high  $\tau_h$  identification efficiency, approximately 50% for the range of  $\tau_h$  energies relevant for this analysis, while keeping the misidentification rate for jets at the level of 1%.

Events are required to have at least one  $Z \rightarrow \ell^+ \ell^-$  candidate, denoted by  $Z_1$ . The invariant mass of the reconstructed  $Z_1$  is required to be  $60 < m_{\ell\ell} < 120$  GeV. The two leptons must have opposite charges, one with  $p_T > 20$  GeV and the other with  $p_T > 10$  GeV, and with  $|\eta| < 2.5$  for the electrons and  $|\eta| < 2.4$  for the muons. If more than one candidate is found, the one with the mass closest to the  $Z$  mass is considered as  $Z_1$ .

Lepton isolation requirements depend on the  $ZZ$  decay mode. For the final states with only electrons and muons, the isolation criteria are based on a combination of the tracker, ECAL, and HCAL information. The standard combined relative isolation is defined as

$$I_{\text{rel}}^{\text{std}} = \left( \sum_i p_{T, \text{track}}^i + \max \left( \sum_j E_{T, \text{ECAL}}^j + \sum_k E_{T, \text{HCAL}}^k - \pi \cdot \Delta R_{\text{max}}^2 \cdot \rho; 0 \right) \right) / p_T^\ell,$$

with the sums running over the charged tracks and the energy deposits in the ECAL and HCAL within a cone around the lepton direction defined by  $\Delta R < \Delta R_{\text{max}} = 0.3$ , where  $\Delta R = \sqrt{(\Delta\eta)^2 + (\Delta\phi)^2}$ , and  $E_T$  stands for the transverse energy. The isolation is made largely insensitive to pileup of pp collisions by correcting for the average energy density,  $\rho$ , measured in cones at randomly chosen locations to sample the average underlying energy in the event. The isolation variable  $I_{\text{rel}}^{\text{std}}$  is required to be less than 0.275 for each lepton. The significance of the impact parameter of each lepton relative to the event vertex ( $S_{3D}$ ) is required to satisfy  $|S_{3D}| < 4$ . The primary vertex is chosen as the vertex with the highest sum of  $p_T^2$  of its constituent tracks.

In the  $2\ell 2\tau$  final states, instead of standard isolation, the leptons from the  $Z_1$  are required to have a combined PF relative isolation  $I_{\text{rel}}^{\text{PF}} < 0.25$ . The  $I_{\text{rel}}^{\text{PF}}$  is defined similarly to  $I_{\text{rel}}^{\text{std}}$ , however in this case the sums run over charged hadrons, photons, and neutral hadrons, all measured in the isolation cone of  $\Delta R < 0.4$  around the lepton direction.

The selection requirements for the second  $Z$ , denoted by  $Z_2$ , also depend on the final state. In the final states with electrons and muons only, the isolation requirements are the same as for the leptons from  $Z_1$ , but  $p_T > 7$  GeV and  $p_T > 5$  GeV are required for electrons and muons, respectively. If the final state is  $\tau_e \tau_\mu$ , the lepton  $p_T$  values are required to exceed 10 GeV. The remaining criteria are identical to those for  $Z_1$ . Since hadronically decaying  $\tau$  leptons have much larger misidentification rates than the other leptons, the isolation requirement based on  $I_{\text{rel}}^{\text{PF}}$  for the electrons and muons in the final states  $\tau_e \tau_h$  and  $\tau_\mu \tau_h$  is changed to 0.15 and 0.1, respectively. A study of inclusive  $Z \rightarrow \tau^+ \tau^-$  production [30] demonstrated that modifying the electron and muon isolation requirements is a more effective way to reduce background in such final states than requiring tighter isolation on  $\tau_h$ . The  $\tau$  leptons are required to have  $p_T > 20$  GeV and  $|\eta| < 2.3$ , and to satisfy the requirements of a loose HPS working point. If

the  $Z_2$  decays to  $\tau_h^+ \tau_h^-$ , both  $\tau_h$  are required to satisfy the requirements of a medium working point of the HPS algorithm. The loose (medium) working point requires the scalar sum of the  $p_T$  of the charged hadrons and  $E_T$  of the neutral hadrons within the isolation cone to be less than 2 GeV (1 GeV). The loose (medium) working point corresponds to a probability of approximately 1% (0.5%) for jets to be misidentified as  $\tau_h$ . Using the medium instead of loose working point leads to a decrease in the  $\tau_h$  reconstruction efficiency from  $\approx 50\%$  to  $\approx 40\%$ .

The invariant mass of the reconstructed  $Z_2$  is required to satisfy  $60 < m_{\ell\ell} < 120$  GeV, when  $Z_2$  decays into  $e^+e^-$  or  $\mu^+\mu^-$ . In the  $2\ell 2\tau$  final states, the visible invariant mass of the reconstructed  $Z_2 \rightarrow \tau^+\tau^-$  is required to satisfy  $30 < m_{\tau\tau}^{\text{vis}} < 80$  GeV. The upper bound reduces contributions from  $Z_2 \rightarrow \ell^+\ell^-$ , where an electron or a muon is not well reconstructed and is misidentified as a  $\tau_h$ . For the  $Z_2 \rightarrow \tau_e\tau_\mu$  final state, the upper bound on  $m_{\tau\tau}$  is increased to 90 GeV, as this state is not produced in  $Z_2 \rightarrow \ell^+\ell^-$  decays. In the final states involving  $\tau_h$ , leptons from the same  $Z$  are required to be separated by  $\Delta R > 0.4$  for the  $Z_1$ , and by  $\Delta R > 0.5$  for the  $Z_2$ .

The major contributions to the background are due to  $Z$  production in association with jets,  $WZ$  production in association with jets, and  $t\bar{t}$ . In all of these cases, a jet or nonisolated lepton is misidentified as an isolated electron, muon, or  $\tau_h$ . The relative contribution of each source of background depends on the final state.

The background estimate is performed in two steps. Firstly, the rate for loosely isolated objects to be misidentified as isolated ones is measured in a control region that does not contain any signal contribution. The misidentification rate is estimated with events in which the  $Z_1$  passes all selection requirements, and which contain an additional probe electron, muon, or  $\tau_h$ . No isolation requirement is applied to the probe. The misidentification rate is defined as the ratio of the number of probe candidates that pass the isolation requirements to the initial number of probe candidates, and is measured as a function of  $p_T$  and  $\eta$  for each lepton flavor.

The second step is to estimate the number of background events in the signal region. The measured misidentification rate is applied to events that pass all selection requirements, including the opposite-charge requirement for the  $Z_2$ , but requiring the candidates to not be isolated.

Theoretical uncertainties on the  $ZZ \rightarrow 2\ell 2\ell'$  acceptance are evaluated using MCFM 6.2 [31], varying QCD scales up and down by a factor of two with respect to the default factorization ( $\mu_F$ ) and renormalization ( $\mu_R$ ) scales  $\mu_F = \mu_R = m_Z$ , where  $m_Z$  is the mass of the  $Z$  boson. The variations in the acceptance are 0.1% ( $q\bar{q} \rightarrow ZZ$ ) and 0.4% ( $gg \rightarrow ZZ$ ) and can be neglected. The uncertainties related to the PDFs are evaluated following the PDF4LHC prescription [32]. Using the CT10 [18], MSTW08 [33], and NNPDF [34] sets, the uncertainties are estimated to be 4% for  $q\bar{q} \rightarrow ZZ$  and 5% for  $gg \rightarrow ZZ$  processes.

The uncertainties on  $Z$ +jets,  $WZ$ +jets, and  $t\bar{t}$  backgrounds reflect the uncertainties on the measured values of the misidentification rates and the limited quantity of data in the control regions in the data and amount to 30–50% depending on the decay channel. The uncertainty on the integrated luminosity is 2.2% [35]. Systematic uncertainties on trigger efficiency (1.5%), lepton identification efficiency, and lepton isolation are evaluated from data. The uncertainties associated with lepton identification and isolation are 1–2% for muons and electrons, and 6–7% for  $\tau_h$ . Uncertainties on energy scales, 3% for  $\tau_h$  and 1–2.5% for electrons, contribute to variations in the shape of the mass spectrum.

Table 1 presents the number of observed events in the signal region in each channel, as well as the expected number of signal events and the estimated number of background events. We observe a total of 54 candidate events in the  $4e$ ,  $4\mu$ , and  $2e2\mu$  channels, compared to the SM expec-

Table 1: The expected yield of ZZ events obtained from simulation and the estimated yield of background events obtained from data, as described in the text, are shown for each decay channel and are summed in the total expected yield ("Total expected"). They are compared to the number of events observed in the signal region. The first uncertainty is statistical while the second one is systematic.

Decay channel	Expected ZZ	Background	Total expected	Observed
eeee	$10.50 \pm 0.04 \pm 0.95$	$0.25 \pm 0.14 \pm 0.07$	$10.75 \pm 0.14 \pm 0.95$	9

tation of  $54.5 \pm 0.3$  (stat.)  $\pm 4.8$  (syst.) events, which includes 1.4 from background processes. In the  $2\ell 2\tau$  channels, 11 candidate events are observed, compared to  $11.7 \pm 0.8$  (stat.)  $\pm 1.0$  (syst.) events expected, including 4.4 from background processes. The reconstructed four-lepton invariant mass distributions are compared to the SM expectations in Figs. 1 (a) and (b) for the sum of the  $4e, 4\mu$ , and  $2e2\mu$  channels, and the sum of all the  $2\ell 2\tau$  channels. The shapes of the signal and background are taken from the MC simulation, with each component normalized to the corresponding estimated value from Table 1. The reconstructed masses in  $2\ell 2\tau$  states ( $m_{2\ell 2\tau}^{\text{vis}}$ ) are shifted downwards with respect to the generated Z masses by about 30% due to the undetected neutrinos in  $\tau$  decays. Figures 1 (c) and (d) demonstrate the relationship between the reconstructed  $Z_1$  and  $Z_2$  masses.

To include all the final states in the calculation of the cross section, a simultaneous fit to the numbers of observed events in all the decay channels is performed. The fit is constrained by the requirement that all the measurements come from the same initial state via different decay modes. It allows for combining many decay modes with either very few or no events observed. The joint likelihood is a combination of the likelihoods for the individual channels, which include the signal and background hypotheses. Each  $\tau$ -lepton decay mode is treated as a separate channel because they are mutually exclusive owing to the methodology adopted for event reconstruction and subsequent event selection. The statistical and systematic uncertainties are introduced in the form of nuisance parameters via log-normal distributions around the estimated central values.

The resulting cross section is measured to be

$$\sigma(\text{pp} \rightarrow \text{ZZ}) = 6.24^{+0.86}_{-0.80} (\text{stat.})^{+0.41}_{-0.32} (\text{syst.}) \pm 0.14 (\text{lumi.}) \text{ pb.}$$

This result is to be compared to the theoretical value of  $6.3 \pm 0.4$  pb calculated with MCFM at NLO for  $q\bar{q} \rightarrow \text{ZZ}$  and LO for  $g g \rightarrow \text{ZZ}$  with the MSTW08 PDFs and for both Z bosons in the mass range  $60 < M_Z < 120$  GeV. This is the most precise published  $\text{pp} \rightarrow \text{ZZ}$  cross section measurement to date, which for the first time extends the  $\text{pp} \rightarrow \text{ZZ} \rightarrow 2\ell 2\ell$  measurement to include final states with hadronically decaying  $\tau$  leptons.

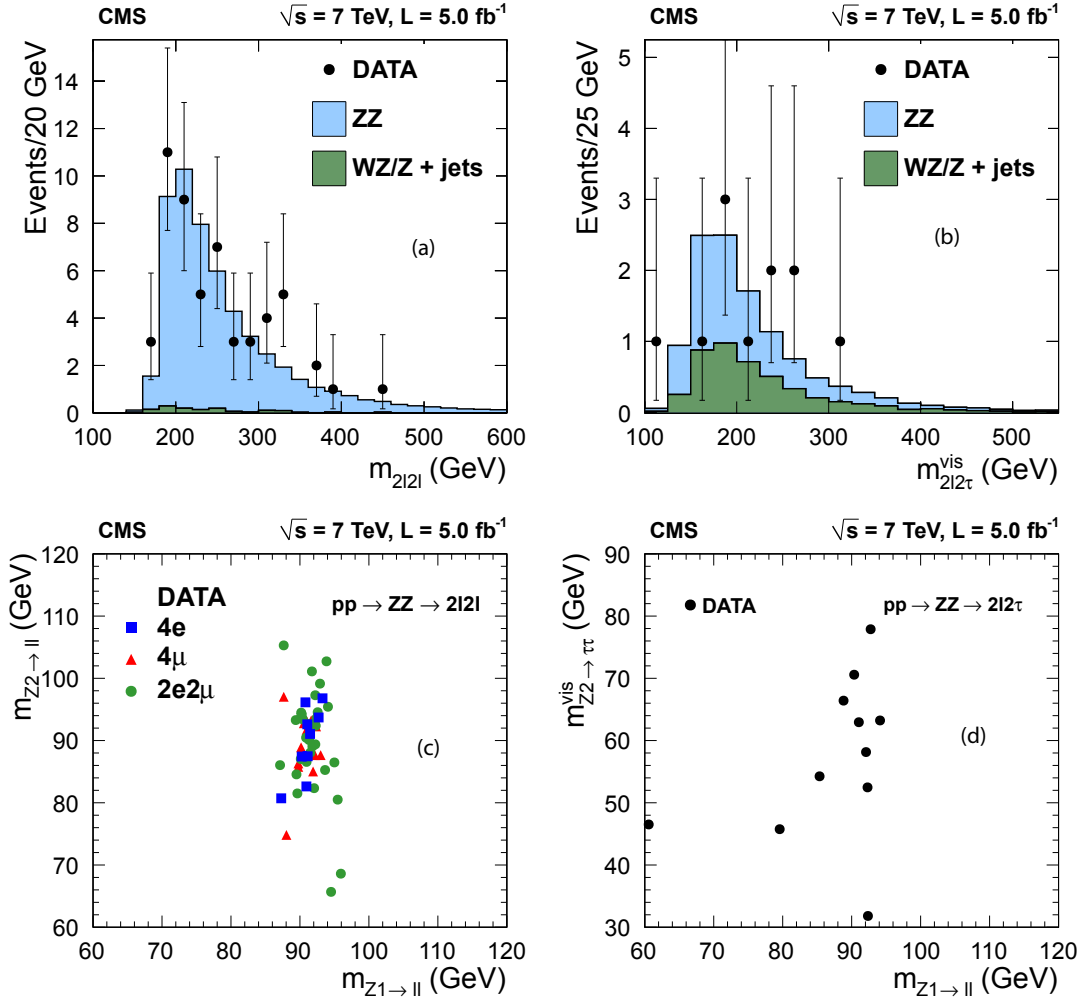

Figure 1: Distributions of the four-lepton reconstructed mass for (a) the sum of the  $4e$ ,  $4\mu$ , and  $2e2\mu$  channels and (b) the sum of the  $2\ell 2\tau$  channels. Points represent the data, and the shaded histograms represent the expected  $ZZ$  signal and the reducible background. The shapes of the signal and background are taken from the MC simulation, with each component normalized to the corresponding estimated value from Table 1. The distributions (c) and (d) demonstrate the relationship between the reconstructed  $Z_1$  and  $Z_2$  masses.

Figure 2: Distribution of the four-lepton reconstructed mass for the sum of the  $4e, 4\mu$ , and the  $2e2\mu$  channels. Points represent the data, and the shaded histograms represent the expected ZZ signal and the reducible background. The dashed and dotted histograms represent the results of the SHERPA simulation for the SM ( $f_4^Z = 0$ ) and in the presence of an ATGC ( $f_4^Z = 0.015$ ), while all the other anomalous couplings are set to zero.

Figure 3: Expected and observed two-dimensional exclusion limits at 95% CL on the anomalous neutral trilinear ZZZ ( $f_{4,5}^Z$ ) and  $ZZ\gamma$  ( $f_{4,5}^\gamma$ ) couplings. The green and yellow bands represent the one and two standard-deviation variations from the expected limit. In calculating the limits, the anomalous couplings that are not shown in the figure are set to zero.

The limits on ATGCs are calculated with the modified frequentist construction  $\text{CL}_s$  [36–38] based on the shape of the four-lepton invariant mass distributions, including the  $4e$ ,  $4\mu$ , and  $2e2\mu$  channels in the likelihood combination. Figure 2 presents the distribution of the four-lepton reconstructed mass for the sum of the  $4e$ ,  $4\mu$ , and  $2e2\mu$  channels. The dashed and dotted histograms represent the results of the SHERPA simulation for the SM ( $f_4^Z = 0$ ) and in the presence of an ATGC ( $f_4^Z = 0.015$ ), while all the other anomalous couplings are set to zero. The presence of ATGCs would be manifested in an increased yield of events at high four-lepton masses. The invariant mass distributions are interpolated from SHERPA simulation for different values of the anomalous couplings. For each distribution only one or two couplings are varied, while all others are set to zero. The fit is performed to find the maximum likelihood value and limits are calculated. To avoid unitarity violation at energies above the scale  $\Lambda$  of new physics, the ATGCs are often modified with a form-factor parametrization of the type  $1/(1 + \hat{s}/\Lambda^2)^2$ , where  $\sqrt{\hat{s}} \approx m_{2\ell 2\ell'}$  is the effective center-of-mass energy of the collision. However, no unitarity violations occur in the sensitive region  $m_{2\ell 2\ell'} \lesssim 1.5 \text{ TeV}$  for bare anomalous couplings of order 0.05 or smaller [39], so we calculate the limits without form-factor scaling. This choice has the advantage of avoiding any bias from energy-dependence assumptions and is exact in the limit in which the scale of new physics is much larger than  $\sqrt{\hat{s}}$ .

Figure 3 presents the expected and observed two-dimensional exclusion limits at 95% confidence level (CL) on the anomalous neutral trilinear  $ZZZ$  and  $ZZ\gamma$  couplings. The green and yellow bands represent the one and two standard-deviation variations from the expected limit. The present limits are dominated by statistical uncertainties. Systematic uncertainties arising from the uncertainty on the theoretical cross section, PDFs, detector efficiencies, and luminosity are introduced in the form of nuisance parameters with log-normal probability density functions. One-dimensional 95% CL limits for the  $f_4^{Z,\gamma}$  and  $f_5^{Z,\gamma}$  anomalous coupling parameters are measured to be

$$-0.011 < f_4^Z < 0.012, \quad -0.012 < f_5^Z < 0.012, \quad -0.013 < f_4^\gamma < 0.015, \quad -0.014 < f_5^\gamma < 0.014.$$

In the one-dimensional fits, all of the ATGC parameters except the one under study are kept fixed to zero. These values extend previous results on vector boson self-interactions and are currently the most stringent limits established for  $ZZZ$  and  $ZZ\gamma$  couplings.

In summary, we have presented an updated measurement of the  $ZZ$  production cross section in proton-proton collisions at 7 TeV in the  $ZZ \rightarrow 2\ell 2\ell'$  decay mode, with  $\ell = e, \mu$  and  $\ell' = e, \mu, \tau$ . The data sample corresponds to an integrated luminosity of  $5.0 \text{ fb}^{-1}$ . The measured cross section  $\sigma(\text{pp} \rightarrow ZZ) = 6.24_{-0.80}^{+0.86} (\text{stat.})_{-0.32}^{+0.41} (\text{syst.}) \pm 0.14 (\text{lumi.}) \text{ pb}$  is consistent with the SM prediction and is the most precise published  $\text{pp} \rightarrow ZZ$  cross section measurement to date. For the first time the  $\text{pp} \rightarrow ZZ \rightarrow 2\ell 2\ell'$  measurements are extended to include final states with hadronically decaying  $\tau$  leptons. Limits on vector-boson self-interactions are established, significantly restricting anomalous  $ZZZ$  and  $ZZ\gamma$  trilinear gauge couplings.

We congratulate our colleagues in the CERN accelerator departments for the excellent performance of the LHC and thank the technical and administrative staffs at CERN and at other CMS institutes for their contributions to the success of the CMS effort. In addition, we gratefully acknowledge the computing centers and personnel of the Worldwide LHC Computing Grid for delivering so effectively the computing infrastructure essential to our analyses. Finally, we acknowledge the enduring support for the construction and operation of the LHC and the CMS detector provided by the following funding agencies: BMWF and FWF (Austria); FNRS and FWO (Belgium); CNPq, CAPES, FAPERJ, and FAPESP (Brazil); MEYS (Bulgaria); CERN; CAS,

MoST, and NSFC (China); COLCIENCIAS (Colombia); MSES (Croatia); RPF (Cyprus); MoER, SF0690030s09 and ERDF (Estonia); Academy of Finland, MEC, and HIP (Finland); CEA and CNRS/IN2P3 (France); BMBF, DFG, and HGF (Germany); GSRT (Greece); OTKA and NKTH (Hungary); DAE and DST (India); IPM (Iran); SFI (Ireland); INFN (Italy); NRF and WCU (Republic of Korea); LAS (Lithuania); CINVESTAV, CONACYT, SEP, and UASLP-FAI (Mexico); MSI (New Zealand); PAEC (Pakistan); MSHE and NSC (Poland); FCT (Portugal); JINR (Armenia, Belarus, Georgia, Ukraine, Uzbekistan); MON, RosAtom, RAS and RFBR (Russia); MSTĐ (Serbia); SEIDI and CPAN (Spain); Swiss Funding Agencies (Switzerland); NSC (Taipei); ThEP-Center, IPST and NSTDA (Thailand); TUBITAK and TAEK (Turkey); NASU (Ukraine); STFC (United Kingdom); DOE and NSF (USA).

†: Deceased

1: Also at Vienna University of Technology, Vienna, Austria

2: Also at National Institute of Chemical Physics and Biophysics, Tallinn, Estonia

3: Also at Universidade Federal do ABC, Santo Andre, Brazil

4: Also at California Institute of Technology, Pasadena, USA

- 5: Also at CERN, European Organization for Nuclear Research, Geneva, Switzerland
- 6: Also at Laboratoire Leprince-Ringuet, Ecole Polytechnique, IN2P3-CNRS, Palaiseau, France
- 7: Also at Suez Canal University, Suez, Egypt
- 8: Also at Zewail City of Science and Technology, Zewail, Egypt
- 9: Also at Cairo University, Cairo, Egypt
- 10: Also at Fayoum University, El-Fayoum, Egypt
- 11: Also at British University in Egypt, Cairo, Egypt
- 12: Now at Ain Shams University, Cairo, Egypt
- 13: Also at National Centre for Nuclear Research, Swierk, Poland
- 14: Also at Université de Haute-Alsace, Mulhouse, France
- 15: Also at Joint Institute for Nuclear Research, Dubna, Russia
- 16: Also at Moscow State University, Moscow, Russia
- 17: Also at Brandenburg University of Technology, Cottbus, Germany
- 18: Also at The University of Kansas, Lawrence, USA
- 19: Also at Institute of Nuclear Research ATOMKI, Debrecen, Hungary
- 20: Also at Eötvös Loránd University, Budapest, Hungary
- 21: Also at Tata Institute of Fundamental Research - HECR, Mumbai, India
- 22: Also at University of Visva-Bharati, Santiniketan, India
- 23: Also at Sharif University of Technology, Tehran, Iran
- 24: Also at Isfahan University of Technology, Isfahan, Iran
- 25: Also at Plasma Physics Research Center, Science and Research Branch, Islamic Azad University, Tehran, Iran
- 26: Also at Facoltà Ingegneria, Università di Roma, Roma, Italy
- 27: Also at Università della Basilicata, Potenza, Italy
- 28: Also at Università degli Studi Guglielmo Marconi, Roma, Italy
- 29: Also at Università degli Studi di Siena, Siena, Italy
- 30: Also at University of Bucharest, Faculty of Physics, Bucuresti-Magurele, Romania
- 31: Also at Faculty of Physics of University of Belgrade, Belgrade, Serbia
- 32: Also at University of California, Los Angeles, Los Angeles, USA
- 33: Also at Scuola Normale e Sezione dell'INFN, Pisa, Italy
- 34: Also at INFN Sezione di Roma; Università di Roma, Roma, Italy
- 35: Also at University of Athens, Athens, Greece
- 36: Also at Rutherford Appleton Laboratory, Didcot, United Kingdom
- 37: Also at Paul Scherrer Institut, Villigen, Switzerland
- 38: Also at Institute for Theoretical and Experimental Physics, Moscow, Russia
- 39: Also at Albert Einstein Center for Fundamental Physics, Bern, Switzerland
- 40: Also at Gaziosmanpasa University, Tokat, Turkey
- 41: Also at Adiyaman University, Adiyaman, Turkey
- 42: Also at Izmir Institute of Technology, Izmir, Turkey
- 43: Also at The University of Iowa, Iowa City, USA
- 44: Also at Mersin University, Mersin, Turkey
- 45: Also at Ozyegin University, Istanbul, Turkey
- 46: Also at Kafkas University, Kars, Turkey
- 47: Also at Suleyman Demirel University, Isparta, Turkey
- 48: Also at Ege University, Izmir, Turkey
- 49: Also at School of Physics and Astronomy, University of Southampton, Southampton, United Kingdom
- 50: Also at INFN Sezione di Perugia; Università di Perugia, Perugia, Italy
- 51: Also at University of Sydney, Sydney, Australia

- 52: Also at Utah Valley University, Orem, USA
- 53: Now at University of Edinburgh, Scotland, Edinburgh, United Kingdom
- 54: Also at Institute for Nuclear Research, Moscow, Russia
- 55: Also at University of Belgrade, Faculty of Physics and Vinca Institute of Nuclear Sciences, Belgrade, Serbia
- 56: Also at Argonne National Laboratory, Argonne, USA
- 57: Also at Erzincan University, Erzincan, Turkey
- 58: Also at Mimar Sinan University, Istanbul, Istanbul, Turkey
- 59: Also at KFKI Research Institute for Particle and Nuclear Physics, Budapest, Hungary
- 60: Also at Kyungpook National University, Daegu, Korea
